#### Abstract

Subsolidus phase equilibria and crystal chemistry were studied for the $\mathrm{La}_{2} \mathrm{O}_{3}-\mathrm{MgO}-\mathrm{TiO}_{2}$ system and for the ternary sections $\mathrm{LaMg}_{1 / 2} \mathrm{Ti}_{1 / 2} \mathrm{O}_{3}-\mathrm{CaTiO}_{3}-\mathrm{La}_{2} \mathrm{O}_{3}$ and $\mathrm{LaMg}_{1 / 2} \mathrm{Ti}_{1 / 2} \mathrm{O}_{3}-\mathrm{CaTiO}_{3}-\mathrm{La}_{0.833} \mathrm{Mg}_{0.25} \mathrm{Ti}_{0.75} \mathrm{O}_{3}$ in the quaternary $\mathrm{La}_{2} \mathrm{O}_{3}-\mathrm{CaO}-\mathrm{MgO}-\mathrm{TiO}_{2}$ system. Dielectric properties (relative permittivity and temperature coefficient of resonant frequency, $\tau_{\mathrm{f}}$ ) were measured at $5-10 \mathrm{GHz}$ and mapped onto the phase equilibria relations to reveal the compositions of temperature-stable ( $\tau_{\mathrm{f}}=0$ ) compounds and mixtures. Phase equilibria relations were obtained by X-ray powder diffraction analysis of approximately 80 specimens prepared by solid-state reactions in air at $\sim 1450^{\circ} \mathrm{C}$. Six ternary phases were found to form in the $\mathrm{La}_{2} \mathrm{O}_{3}-\mathrm{MgO}-\mathrm{TiO}_{2}$ system, including the three previously reported compounds $\mathrm{LaMg}_{1 / 2} \mathrm{Ti}_{1 / 2} \mathrm{O}_{3}, \quad \mathrm{La}_{5} \mathrm{Mg}_{0.5} \mathrm{Ti}_{3.5} \mathrm{O}_{15}$, and " $\mathrm{La}_{6} \mathrm{MgTi}_{4} \mathrm{O}_{18}{ }^{8}$ "; and the new phases $\mathrm{La}_{10} \mathrm{MgTi}_{9} \mathrm{O}_{34}$, $\mathrm{La}_{9} \mathrm{Mg}_{0.5} \mathrm{Ti}_{8.5} \mathrm{O}_{31}$, and a perovskite-type solid solution ( $1-x$ ) $\mathrm{LaMg}_{1 / 2} \mathrm{Ti}_{1 / 2} \mathrm{O}_{3}-x \mathrm{La}_{2 / 3} \mathrm{TiO}_{3}(0 \leqslant x \leqslant 0.5$ ). The phase previously reported as " $\mathrm{La}_{6} \mathrm{MgTi}_{4} \mathrm{O}_{18}$ " was found to form off-composition, apparently as a point compound, at $\mathrm{La}_{6} \mathrm{Mg}_{0.913} \mathrm{Ti}_{4.04} \mathrm{O}_{18}$. Indexed experimental X-ray powder diffraction patterns are given for $\mathrm{LaMg}_{1 / 2} \mathrm{Ti}_{1 / 2} \mathrm{O}_{3}, \mathrm{La}_{5} \mathrm{Mg}_{0.5} \mathrm{Ti}_{3.5} \mathrm{O}_{15}, \mathrm{La}_{6} \mathrm{Mg}_{0.913} \mathrm{Ti}_{4.04} \mathrm{O}_{18}$, $\mathrm{La}_{10} \mathrm{MgTi}_{9} \mathrm{O}_{34}$, and $\mathrm{La}_{9} \mathrm{Mg}_{0.5} \mathrm{Ti}_{8.5} \mathrm{O}_{31} . \mathrm{LaMg}_{1 / 2} \mathrm{Ti}_{1 / 2} \mathrm{O}_{3}$ exhibits a slightly distorted perovskite structure with ordered $B$-cations $\left(P 2_{1} / n ; a=5.5608(2) \AA, b=5.5749(3) \AA, c=7.8610(5) \AA, \beta=90.034(4)^{\circ}\right) . \mathrm{La}_{5} \mathrm{Mg}_{0.5} \mathrm{Ti}_{3.5} \mathrm{O}_{15}(P \overline{3} m 1 ; a=5.5639(1), c=10.9928(5) \AA)$ and $\mathrm{La}_{6} \mathrm{Mg}_{0.913} \mathrm{Ti}_{4.04} \mathrm{O}_{18}(R 3 m ; a=5.5665(1), c=39.7354(9) \AA$ ) are $n=5$ and $n=6$ members, respectively, of the (111) perovskiteslab series $A_{n} B_{n-1} \mathrm{O}_{3 n}$. The new phases $\mathrm{La}_{10} \mathrm{MgTi}_{9} \mathrm{O}_{34}(a=5.5411(2), b=31.3039(9), c=3.9167(1) \AA)$ and $\mathrm{La}_{9} \mathrm{Mg}_{0.5} \mathrm{Ti}_{8.5} \mathrm{O}_{31}$ ( $a=5.5431(2), b=57.055(1), c=3.9123(1) \AA)$ are $n=5$ and $n=4.5$ members, respectively, of the (110) perovskite-slab series $A_{n} B_{n} \mathrm{O}_{3 n+2}$, which exhibit orthorhombic subcells; electron diffraction revealed monoclinic superlattices with doubled $c$-parameters for both compounds. Extensive perovskite-type solid solutions form in the ternary sections $\mathrm{LaMg}_{1 / 2} \mathrm{Ti}_{1 / 2} \mathrm{O}_{3}-\mathrm{CaTiO}_{3}-\mathrm{La}_{2} \mathrm{O}_{3}$ and $\mathrm{LaMg}_{1 / 2} \mathrm{Ti}_{1 / 2} \mathrm{O}_{3}-\mathrm{CaTiO}_{3}-\mathrm{La}_{0.833} \mathrm{Mg}_{0.25} \mathrm{Ti}_{0.75} \mathrm{O}_{3}$. The $\mathrm{La}_{2} \mathrm{O}_{3}-\mathrm{MgO}-\mathrm{TiO}_{2}$ system contains two regions of temperature-stable ( $\tau_{\mathrm{f}}=0$ ) compositions. The quaternary $\mathrm{La}_{2} \mathrm{O}_{3}-\mathrm{CaO}-\mathrm{MgO}-\mathrm{TiO}_{2}$ system contains an extensive single-phase perovskite-type volume through which passes a surface of temperature-stable compositions with permittivities projected to be in the $40-50$ range. Traces of this surface occur as lines of $\tau_{\mathrm{f}}=0$ perovskite-type phases in the ternary sections $\mathrm{LaMg}_{1 / 2} \mathrm{Ti}_{1 / 2} \mathrm{O}_{3}-\mathrm{CaTiO}_{3}-\mathrm{La}_{2} \mathrm{O}_{3}$ and $\mathrm{LaMg}_{1 / 2} \mathrm{Ti}_{1 / 2} \mathrm{O}_{3^{-}}$ $\mathrm{CaTiO}_{3}-\mathrm{La}_{0.833} \mathrm{Mg}_{0.25} \mathrm{Ti}_{0.75} \mathrm{O}_{3}$. ## 1. Introduction

Complex titanates, niobates, and tantalates display dielectric properties rendering them useful in communication systems as enabling components such as resonators and filters [1-6]. These ceramics are referred to as "microwave dielectrics", and include numerous

[^0]perovskite-related $A B \mathrm{O}_{3}$-type phases which exhibit dielectric properties strongly affected by $A$ - and/or $B$ site cation substitution and/or ordering [7]. The present study was motivated by the perovskite-like solid solution occurring in the quaternary $\mathrm{La}_{2} \mathrm{O}_{3}-\mathrm{CaO}-$ $\mathrm{MgO}-\mathrm{TiO}_{2}$ system between $\mathrm{LaMg}_{1 / 2} \mathrm{Ti}_{1 / 2} \mathrm{O}_{3}$ and $\mathrm{CaTiO}_{3}$. The dielectric properties of the endmembers are markedly different: $\mathrm{LaMg}_{1 / 2} \mathrm{Ti}_{1 / 2} \mathrm{O}_{3}$ exhibits a permittivity ( $\varepsilon$ ) of 33 with a temperature coefficient of resonant frequency $\left(\tau_{f}\right)$ of $-90 \mathrm{ppm} /{ }^{\circ} \mathrm{C}$ [3], whereas the
permittivity of $\mathrm{CaTiO}_{3}$ is much higher (180) with a $\tau_{\mathrm{f}}$ of opposite sign $\left(+800 \mathrm{ppm} /{ }^{\circ} \mathrm{C}\right)[7,8]$. A complete solid solution forms between them, and temperature-stability $\left(\tau_{\mathrm{f}}=0\right)$ is achieved at $44: 56 \mathrm{LaMg}_{1 / 2} \mathrm{Ti}_{1 / 2} \mathrm{O}_{3}: \mathrm{CaTiO}_{3}$ with a permittivity of 48 [3]. Permittivities higher than 50 (and small positive $\tau_{\mathrm{f}}$ values) are obtained with $\mathrm{CaTiO}_{3}$ concentrations above $59 \mathrm{~mol} \%$, rendering the system of interest as a low-cost ceramic for 900 MHz applications. The present study was carried out to elucidate the subsolidus phase equilibria about the $\mathrm{LaMg}_{1 / 2} \mathrm{Ti}_{1 / 2} \mathrm{O}_{3}: \mathrm{CaTiO}_{3}$ solid solution in order to provide information that could be used to tailor its dielectric properties through the preparation of thermodynamically stable mixtures. The primary focus was determination of phase relations in the $\mathrm{La}_{2} \mathrm{O}_{3}-\mathrm{MgO}-$ $\mathrm{TiO}_{2}$ system, which was the least-studied ternary subsystem, as well as phase equilibria involving the endmembers $\mathrm{LaMg}_{1 / 2} \mathrm{Ti}_{1 / 2} \mathrm{O}_{3}$ and $\mathrm{CaTiO}_{3}$.

### 1.1. Overview of the subsystems and previous work

Three compounds form in the $\mathbf{M g O}-\mathbf{T i O}_{\mathbf{2}}$ system: $\mathrm{Mg}_{2} \mathrm{TiO}_{4}$ (inverse spinel-type), $\mathrm{MgTiO}_{3}$ (Geikielite, ilmenite-type) and $\mathrm{MgTi}_{2} \mathrm{O}_{5}$ (pseudobrookite-type). ${ }^{1}$ Several reports have indicated that no binary compounds form in the $\mathbf{M g O}-\mathbf{L a}_{2} \mathbf{O}_{\mathbf{3}}$ system (see footnote 1). The binary $\mathbf{L a}_{\mathbf{2}} \mathbf{O}_{\mathbf{3}}-\mathbf{T i O}_{\mathbf{2}}$ system is more complex (see footnote 1). Early studies indicated the formation of three compounds: $\mathrm{La}_{2} \mathrm{TiO}_{5}, \mathrm{La}_{2} \mathrm{Ti}_{2} \mathrm{O}_{7}$, and $\mathrm{La}_{4} \mathrm{Ti}_{9} \mathrm{O}_{24}$ [9]. A later study reported a fourth compound, $\mathrm{La}_{4} \mathrm{Ti}_{3} \mathrm{O}_{12}$, which forms with a perovskite-derived 12layer hexagonal crystal structure, and which decomposes above $1450^{\circ} \mathrm{C}$ to $\mathrm{La}_{2} \mathrm{TiO}_{5}$ and $\mathrm{La}_{2} \mathrm{Ti}_{2} \mathrm{O}_{7}$ [10-12]. The structure of $\mathrm{La}_{2} \mathrm{TiO}_{5}$ features $\mathrm{Ti}^{4+}$ in five-fold trigonal bypyramidal coordination [13], whereas $\mathrm{La}_{2} \mathrm{Ti}_{2} \mathrm{O}_{7}$ adopts a perovskite-slab type structure $[14,15] . \mathrm{La}_{4} \mathrm{Ti}_{9} \mathrm{O}_{24}[16]$ was confirmed to be isostructural with $\mathrm{Nd}_{4} \mathrm{Ti}_{9} \mathrm{O}_{24}[17,18]$, which exhibits an orthorhombic framework-type structure featuring pairs of edge-sharing $\left[\mathrm{TiO}_{6}\right]$ octahedra with six- and eight-fold coordinated $\mathrm{Nd}^{3+}$. A fifth compound, cation-deficient perovskite-related " $\mathrm{La}_{2 / 3} \mathrm{TiO}_{3}$ " [19], does not occur as such in the $\mathrm{La}_{2} \mathrm{O}_{3}-\mathrm{TiO}_{2}$ system, but is stabilized by small amounts of $\mathrm{Ti}^{3+}$, by partial filling of the $A$-sites with mono- or divalent cations [12], or by partial substitution of $\mathrm{Ti}^{4+}$ with trivalent cations [3,20].

Three compounds have been reported to form in the ternary $\mathbf{L a}_{2} \mathbf{O}_{\mathbf{3}}-\mathbf{M g O}-\mathbf{T i O} \mathbf{2}_{2}$ system: $\mathrm{LaMg}_{1 / 2} \mathrm{Ti}_{1 / 2} \mathrm{O}_{3}$, $\mathrm{La}_{5} \mathrm{Mg}_{0.5} \mathrm{Ti}_{3.5} \mathrm{O}_{15}$, and $\mathrm{La}_{6} \mathrm{MgTi}_{4} \mathrm{O}_{18}$ [11,21,22]. Perovs-kite-like $\mathrm{LaMg}_{1 / 2} \mathrm{Ti}_{1 / 2} \mathrm{O}_{3}$ has been variously described as cubic, orthorhombic, or monoclinic [21,23]; however, a

[^1]recent Rietveld analysis of X-ray powder diffraction data confirms monoclinic symmetry [23] with nearcomplete ordering of $\mathrm{Mg}^{2+}$ and $\mathrm{Ti}^{4+}$ on the $B$-sites, analogous to $\mathrm{NdMg}_{1 / 2} \mathrm{Ti}_{1 / 2} \mathrm{O}_{3}$ [24]. $\mathrm{La}_{5} \mathrm{Mg}_{0.5} \mathrm{Ti}_{3.5} \mathrm{O}_{15}$ and $\mathrm{La}_{6} \mathrm{MgTi}_{4} \mathrm{O}_{18}$ were reported as $n=5$ and $n=6$ members of the hexagonal homologous series $A_{n} B_{n-1} \mathrm{O}_{3 n}[11,22]$. These structures feature perovskitetype slabs (with thickness $n-1 \quad\left[B \mathrm{O}_{6}\right]$ octahedra) extending parallel to $(111)_{\text {perov }}$, and separated by a layer of ordered $B$-cation vacancies. A study of phase relations in the $\mathrm{La}_{2} \mathrm{O}_{3}-\mathrm{MgO}-\mathrm{TiO}_{2}$ system at $1200^{\circ} \mathrm{C}$ [25] confirmed the formation of these three compounds; however, a large single-phase solid solution was reported about $\mathrm{LaMg}_{1 / 2} \mathrm{Ti}_{1 / 2} \mathrm{O}_{3}$ suggesting extensive dissolution of $\mathrm{MgTiO}_{3}$, which would apparently require the unusual substitution of $\mathrm{Mg}^{2+}$ on the $A$-sites of the perovskite structure.

A study of phase relations in the $\mathbf{C a O}-\mathbf{M g O}-\mathbf{T i O}_{\mathbf{2}}$ system reported no ternary compound formation (see footnote 1) [26]. The $\mathbf{C a O}-\mathbf{M g O}-\mathbf{L a}_{2} \mathbf{O}_{\mathbf{3}}$ system has apparently not been studied, but extensive compound formation would not be expected since no compounds (except solid solutions of the components) have been reported to form along each of the binaries (see footnote 1). In the $\mathrm{La}_{2} \mathbf{O}_{3}-\mathbf{C a O}-\mathbf{T i O}_{2}$ system a number of compounds have been reported as well as equilibria involving $\mathrm{CaTiO}_{3}$. Along the composition line $\mathrm{La}_{4} \mathrm{Ti}_{3} \mathrm{O}_{12}-\mathrm{CaTiO}_{3}$, the compounds $\mathrm{La}_{4} \mathrm{CaTi}_{4} \mathrm{O}_{15}$ and $\mathrm{La}_{4} \mathrm{Ca}_{2} \mathrm{Ti}_{5} \mathrm{O}_{18}$ were reported to form $[11,22,27,28]$ as $n=5$ and $n=6$ members of the hexagonal, perovskiteslab homologous series $A_{n} B_{n-1} \mathrm{O}_{3 n}$. These compounds are analogous to $\mathrm{La}_{5} \mathrm{Mg}_{0.5} \mathrm{Ti}_{3.5} \mathrm{O}_{15}$ and $\mathrm{La}_{6} \mathrm{MgTi}_{4} \mathrm{O}_{18}$, respectively, mentioned above. Three other compounds along the composition line $\mathrm{La}_{2} \mathrm{Ti}_{2} \mathrm{O}_{7}-\mathrm{CaTiO} 3$ have been reported and characterized: $\mathrm{La}_{8} \mathrm{CaTi}_{9} \mathrm{O}_{31}, \mathrm{La}_{4} \mathrm{CaTi}_{5} \mathrm{O}_{17}$, and $\mathrm{La}_{4} \mathrm{Ca}_{2} \mathrm{Ti}_{6} \mathrm{O}_{20}[15,28-33]$. These phases are $n=4.5$, $n=5$, and $n=6$ members, respectively, of the perovs-kite-related series $A_{n} B_{n} \mathrm{O}_{3 n+2}$, which feature crystal structures built from perovskite-type slabs that extend parallel to the $(110)_{\text {perov }}$ planes. $\mathrm{CaTiO}_{3}$ forms an extensive solid solution $(1-x) \mathrm{CaTiO}_{3}-x \mathrm{La}_{2 / 3} \mathrm{TiO}_{3}$, with $x$-values as high as 0.96 (see footnote 1) [34-36]. $\mathrm{CaTiO}_{3}$ was also reported to dissolve up to $40 \mathrm{~mol} \%$ $\mathrm{La}_{2} \mathrm{O}_{3}$ [37], resulting in the perovskite-related endmember $\mathrm{La}_{4} \mathrm{Ca}_{3} \mathrm{Ti}_{3} \mathrm{O}_{15}$. A recent study has characterized the details of cation ordering, symmetry changes, and dielectric properties that occur in this solid solution [38].

## 2. Experimental methods

Approximately 80 polycrystalline specimens $(3-4 \mathrm{~g}$ each) were prepared by solid-state reactions using $\mathrm{La}_{2} \mathrm{O}_{3}$ ( $99.99 \%$, dried at $850^{\circ} \mathrm{C}$ immediately prior to weighing), $\mathrm{CaCO}_{3}\left(99.99 \%\right.$ ), $\mathrm{MgCO}_{3}$ (high-purity, pre-analyzed by thermogravimetric analysis) and $\mathrm{TiO}_{2}$ (phosphate-free).

Prior to each heat treatment, samples were ground with an agate mortar and pestle for 15 min , pelletized, and placed on sacrificial powder of the same composition on Pt foil supported by alumina ceramic. After an initial overnight calcine at $950^{\circ} \mathrm{C}$, multiple $2-7 \mathrm{~d}$ heatings (with intermediate grinding and re-pelletizing) were carried out at $\sim 1450^{\circ} \mathrm{C}$. Samples were furnace-cooled to $\sim 700^{\circ} \mathrm{C}$ and then air-quenched on the bench-top. Typically, four to five heatings were required to attain equilibrium, which was presumed when no further changes could be detected in the weakest peaks observed in the X-ray powder diffraction patterns. In the $\mathrm{La}_{2} \mathrm{O}_{3}-$ $\mathrm{MgO}-\mathrm{TiO}_{2}$ system, minima in the solidus temperatures were observed at $1460^{\circ} \mathrm{C}$ and $1470^{\circ} \mathrm{C}$ near the compositions 0.4048:0.0119:0.5833 and 0.2000:0.3200: 0.4800 molar ratios $\frac{1}{2} \mathrm{La}_{2} \mathrm{O}_{3}: \mathrm{MgO}: \mathrm{TiO}_{2}$, respectively.

Phase assemblages were ascertained using X-ray powder diffraction data, obtained with a Philips ${ }^{2}$ diffractometer equipped with incident Soller slits, theta-compensating slit and a graphite monochromator, and a scintillation detector. Samples were mounted in welled glass slides. Patterns were collected at ambient temperatures using $\mathrm{Cu} K \alpha$ radiation with a $0.02^{\circ} 2 \theta$ step size and a 2 s count time; longer scans $\left(0.015^{\circ}\right.$ step, 4 s count) were carried out to obtain data for least-squares refinement of lattice parameters. Intensity data measured as relative peak heights above background of hand-picked peaks were obtained using the Siemens DIFFRAC5000 second derivative peak locate program. The observed $2 \theta$ line positions reported here have been corrected using SRM 660, $\mathrm{LaB}_{6}$ [39], as an external calibrant. Lattice parameters were refined using the corrected powder diffraction data ( $2 \theta$ values, $\mathrm{Cu} K \alpha_{1}=1.540562 \AA$ ) with the least-squares program CELLSVD [40]. Figures of merit $\left(F_{\mathrm{N}}\right)$ for indexed powder patterns were calculated according to Ref. [41]. The GSAS package [42] was used to calculate powder patterns from single-crystal data. Selected specimens were analyzed using transmission electron microscopy. The TEM specimens were prepared by conventional polishing, dimpling, and ion-thinning. The specimens were examined in a Philips EM 430 TEM operated at 200 kV .

Dielectric properties were measured at microwave frequencies using sintered pellets either $\sim 8$ or $\sim 11 \mathrm{~mm}$ in diameter and $\sim 5 \mathrm{~mm}$ high. Pellet densities ( $\rho_{\text {obs }} / \rho_{\text {calc }}$ ) were determined geometrically. Measurements of the $\mathrm{TE}_{01 \delta}$ resonant mode were carried out using an HP 8720D Vector Network Analyzer and a gold-plated aluminum test cavity ( $\sim 38 \mathrm{~mm}$ in diameter by $\sim 25 \mathrm{~mm}$

[^2]high); unloaded quality factor $Q$ (where $Q=1 / \tan \delta$; $\tan \delta=$ dielectric loss tangent) was measured at ambient temperature using the transmission method [43]. Relative permittivity ( $\varepsilon_{\text {obs }}$ ) was calculated from the sample size and resonant frequency. The temperature coefficient of resonant frequency $\left(\tau_{\mathrm{f}}\right)$ was measured for each sample between the two points of $25^{\circ} \mathrm{C}$ and $60^{\circ} \mathrm{C}$ using an environmental chamber. For samples with high dielectric loss (i.e., low quality factors and therefore very broad resonance signals), $\varepsilon$ values were verified by capacitance measurements at 100 kHz using copper foil electrodes and a HP 4274A LCR meter. Permittivity values were corrected ( $\varepsilon_{\text {corr }}$ ) to theoretical density using an effective-medium formalism [44]. The uncertainties in the corrected permittivity values are approximately $\pm 3 \%$ and are dominated by the estimates of pore volume. The reproducibility of $Q$ measurements was $\pm 5 \%$; the reproducibility of $\tau_{f}$ measurements was approximately $\pm 2 \mathrm{ppm} /{ }^{\circ} \mathrm{C}$.

## 3. Results and discussion

Subsolidus phase equilibria relations were determined for the $\mathrm{La}_{2} \mathrm{O}_{3}-\mathrm{MgO}-\mathrm{TiO}_{2}$ system (Figs. 1 and 2) and for two ternary sections in the quaternary $\mathrm{La}_{2} \mathrm{O}_{3}-\mathrm{CaO}-$ $\mathrm{MgO}-\mathrm{TiO}_{2}$ system: $\mathrm{LaMg}_{1 / 2} \mathrm{Ti}_{1 / 2} \mathrm{O}_{3}-\mathrm{CaTiO}_{3}-\mathrm{La}_{2} \mathrm{O}_{3}$ and $\quad \mathrm{LaMg}_{1 / 2} \mathrm{Ti}_{1 / 2} \mathrm{O}_{3}-\mathrm{CaTiO}_{3}-\mathrm{La}_{0.833} \mathrm{Mg}_{0.25} \mathrm{Ti}_{0.75} \mathrm{O}_{3}$. All dielectric properties measured in the present study are collected in Table 1 and will be discussed in the corresponding sections below. The letter designations for compounds in Table 1 refer to the labels given in Fig. 2.

## 3.1. $\mathrm{La}_{2} \mathrm{O}_{3}-\mathrm{MgO}-\mathrm{TiO}_{2}$ system

The subsolidus phase equilibria relations found in the present study are shown in Fig. 1. Six ternary phases were found, as indicated in Fig. 2 (A-F), including an extensive solid solution along the composition line between $\mathrm{LaMg}_{1 / 2} \mathrm{Ti}_{1 / 2} \mathrm{O}_{3}$ and $\mathrm{La}_{2 / 3} \mathrm{TiO}_{3}(\mathbf{B})$. The X-ray powder diffraction data for $\mathrm{LaMg}_{1 / 2} \mathrm{Ti}_{1 / 2} \mathrm{O}_{3}$ (A) were indexed with a monoclinic unit cell (Table 2), in agreement with other work [23] and analogously to $\mathrm{NdMg} \mathrm{I}_{1 / 2} \mathrm{Ti}_{1 / 2} \mathrm{O}_{3}$ [24]. The relative permittivity obtained for $\mathrm{LaMg}_{1 / 2} \mathrm{Ti}_{1 / 2} \mathrm{O}_{3}$ was 27 and is within the range of values reported for this compound [23].

### 3.1.1. $L a_{n}(\mathrm{Mg}, \mathrm{Ti})_{n-1} O_{3 n}$ (111) perovskite-slab compounds

Formation of the two previously reported $n=5$ and $n=6$ members $[11,22,25]$ was confirmed. The $n=5$ phase $\mathrm{La}_{5} \mathrm{Mg}_{0.5} \mathrm{Ti}_{3.5} \mathrm{O}_{15}(\mathbf{C})$ formed readily and apparently as a point compound. All peaks observed in the X-ray powder diffraction pattern could be indexed with a unit cell and space group analogous to that reported in

Fig. 1. Subsolidus phase equilibria relations determined for the $\mathrm{La}_{2} \mathrm{O}_{3}-\mathrm{MgO}-\mathrm{TiO}_{2}$ system from X-ray powder diffraction studies of specimens prepared in air at $\sim 1450^{\circ} \mathrm{C}$. Six ternary phases, including an extensive solid solution along the composition line between $\mathrm{LaMg}_{1 / 2} \mathrm{Ti}_{1 / 2} \mathrm{O}_{3}$ and $\mathrm{La}_{2 / 3} \mathrm{TiO}_{3}$, were found to form.

Fig. 2. Expanded region of the $\mathrm{La}_{2} \mathrm{O}_{3}-\mathrm{MgO}-\mathrm{TiO}_{2}$ system showing the ternary phases that form. $\mathbf{A}=$ perovskite-like $\mathrm{LaMg}_{1 / 2} \mathrm{Ti}_{1 / 2} \mathrm{O}_{3}$, which forms the solid solution $(\mathbf{B})(1-x) \mathrm{LaMg}_{1 / 2} \mathrm{Ti}_{1 / 2} \mathrm{O}_{3-x} \mathrm{La}_{2 / 3} \mathrm{TiO}_{3}, 0.0 \leqslant x \leqslant 0.5$. As shown here, this solid solution "has width", and extends toward the $\mathrm{La}_{2} \mathrm{O}_{3}-\mathrm{TiO}_{2}$ binary to form a narrow, perovskite-like single-phase region. Compounds $\mathbf{C}$ and $\mathbf{D}$ (along with $\mathrm{La}_{4} \mathrm{Ti}_{3} \mathrm{O}_{12}$ ) are members of the hexagonal (or trigonal) defect-perovskite homologous series $A_{n} B_{n-1} \mathrm{O}_{3 n}$ : $\mathbf{C}=\mathrm{La}_{5} \mathrm{Mg}_{0.5} \mathrm{Ti}_{3.5} \mathrm{O}_{15}(n=5), \mathbf{D}=\mathrm{La}_{6} \mathrm{Mg}_{0.913} \mathrm{Ti}_{4.04} \mathrm{O}_{18}(n=6)$. $\mathbf{E}$ and $\mathbf{F}$ (along with $\mathrm{La}_{2} \mathrm{Ti}_{2} \mathrm{O}_{7}=\mathrm{La}_{4} \mathrm{Ti}_{4} \mathrm{O}_{14}$ ) are members of the homologous series $A_{n} B_{n} \mathrm{O}_{3 n+2}$, which features slabs ( $n\left[B \mathrm{O}_{6}\right]$ octahedra thick) of the perovskite structure extending parallel to the perovskite (110) planes: $\mathbf{E}=\mathrm{La}_{10} \mathrm{MgTi}_{9} \mathrm{O}_{34}(n=5), \mathbf{F}=\mathrm{La}_{9} \mathrm{Mg}_{0.5} \mathrm{Ti}_{8.5} \mathrm{O}_{31}(n=4.5$, alternating slab thicknesses of 4 and 5 octahedra).
a single-crystal study of $\mathrm{Ba}_{5} \mathrm{Nb}_{4} \mathrm{O}_{15}$ [45]; the results are given in Table 3. The powder pattern calculated using the refined unit cell (Table 3), the positional parameters and space group for $\mathrm{Ba}_{5} \mathrm{Nb}_{4} \mathrm{O}_{15}$ [45], and assuming disordered $\mathrm{Mg}^{2+}$ and $\mathrm{Ti}^{4+}$ on the $B$-sites matched the observed pattern, suggesting that $\mathrm{La}_{5} \mathrm{Mg}_{0.5} \mathrm{Ti}_{3.5} \mathrm{O}_{15}$ and $\mathrm{Ba}_{5} \mathrm{Nb}_{4} \mathrm{O}_{15}$ are isostructural. In contrast, the $n=6$ phase formed sluggishly with broad powder diffraction lines, and stoichiometric $\mathrm{La}_{6} \mathrm{MgTi}_{4} \mathrm{O}_{18}$ specimens al-
ways contained small amounts of $\mathrm{LaMg}_{1 / 2} \mathrm{Ti}_{1 / 2} \mathrm{O}_{3}$. Preparation of closely spaced compositions indicated that the $n=6$ phase forms as a point compound at the cation-deficient stoichiometry $\mathrm{La}_{6} \mathrm{Mg}_{0.913} \mathrm{Ti}_{4.04} \square_{0.047} \mathrm{O}_{18}$ (D), which corresponds to $1 \% B$-cation vacancies ( $\square$ ). Inspection of this sample by TEM found a highly defective sample with the dominant phase having the $n=6$ type structure. X-ray powder diffraction data for a $\mathrm{La}_{6} \mathrm{Mg}_{0.913} \mathrm{Ti}_{4.04} \mathrm{O}_{18}$ sample annealed for 2 weeks at

Table 1
Dielectric properties of selected compounds found in the $\mathrm{La}_{2} \mathrm{O}_{3}-\mathrm{CaO}-\mathrm{MgO}-\mathrm{TiO}_{2}$ system.

${ }^{\text {a }}$ No attempt was made to optimize $Q$-values.
$1475^{\circ} \mathrm{C}$ are given in Table 4 and were indexed analogously to $\mathrm{Sr}_{6} \mathrm{TiNb}_{4} \mathrm{O}_{18}$ [46]. The powder pattern calculated using the refined unit cell (Table 4), the positional parameters and space group reported in the single-crystal study of $\mathrm{Sr}_{6} \mathrm{TiNb}_{4} \mathrm{O}_{18}$ [46], and assuming disordered $\mathrm{Mg}^{2+}$ and $\mathrm{Ti}^{4+}$ on the $B$-sites matched the observed pattern, suggesting that $\mathrm{La}_{6} \mathrm{Mg}_{0.913} \mathrm{Ti}_{4.04} \mathrm{O}_{18}$ and $\mathrm{Sr}_{6} \mathrm{TiNb}_{4} \mathrm{O}_{18}$ are isostructural.
The crystal structures of $\mathrm{La}_{5} \mathrm{Mg}_{0.5} \mathrm{Ti}_{3.5} \mathrm{O}_{15}$ and $\mathrm{La}_{6} \mathrm{Mg}_{0.913} \mathrm{Ti}_{4.04} \mathrm{O}_{18}$ are shown in Fig. 3 [47]. As found for other $A_{n} B_{n-1} \mathrm{O}_{3 n}$ homologs, they display unit cells with similar $a$-parameters, and $c$-parameters that reflect the number of close-packed layers (here, at $2.2 \AA /$ layer) in the unit cell (five for $n=5$ and eighteen for $n=6$ ). The solid solution indicated between $\mathrm{La}_{4} \mathrm{Ti}_{3} \mathrm{O}_{12}(n=4)$ and $\mathrm{La}_{5} \mathrm{Mg}_{0.5} \mathrm{Ti}_{3.5} \mathrm{O}_{15}(\mathbf{C}, n=5)$ (Figs. 1 and 2) likely occurs by the formation of intergrowths of the two structures.

### 3.1.2. $L a_{n}(\mathrm{Mg}, \mathrm{Ti})_{n} \mathrm{O}_{3 n+2}$ (110) perovskite-slab compounds

The present study found two phases, $\mathrm{La}_{10} \mathrm{MgTi}_{9} \mathrm{O}_{34}$ (compound $\mathbf{E}$ ) and $\mathrm{La}_{9} \mathrm{Mg}_{0.5} \mathrm{Ti}_{8.5} \mathrm{O}_{31}$ (compound $\mathbf{F}$ ), which have not been previously reported. X-ray powder diffraction data for $\mathrm{La}_{10} \mathrm{MgTi}_{9} \mathrm{O}_{34}$ are given in Table 5 and were indexed analogously to $\mathrm{Sr}_{5} \mathrm{TiNb}_{4} \mathrm{O}_{17}$ [48]. The powder pattern calculated using the refined unit cell
(Table 5), the positional parameters and space group reported in the single-crystal study of $\mathrm{Sr}_{5} \mathrm{TiNb}_{4} \mathrm{O}_{17}$ [48], and assuming disordered $\mathrm{Mg}^{2+}$ and $\mathrm{Ti}^{4+}$ on the $B$-sites matched the observed pattern. These results suggest that $\mathrm{La}_{10} \mathrm{MgTi}_{9} \mathrm{O}_{34}$ is an $n=5$ member of the (110) perovskite-slab homologous series $A_{n} B_{n} \mathrm{O}_{3 n+2}$, several of which have been found in the $\mathrm{La}_{2} \mathrm{O}_{3}-\mathrm{CaO}-\mathrm{TiO}_{2}$ [15,29-32] as well as other systems [48].

As shown in Fig. 4, the $A_{n} B_{n} \mathrm{O}_{3 n+2}$ structures consist of slabs of the distorted perovskite structure sliced parallel to the parent (110) perovskite planes, with $n$ denoting the width of the slabs in number of $\left[B \mathrm{O}_{6}\right]$ octahedra. These homologs exhibit orthorhombic subcells with similar $a-(\sim 5.5 \AA)$ and $c$ - $(\sim 3.9 \AA)$ parameters, and variable $b$-parameters that reflect slab thickness and translational symmetry-they are readily distinguished by characteristic diffraction lines below $15^{\circ} 2 \theta$. Many $A_{n} B_{n} \mathrm{O}_{3 n+2}$ structures feature sequences of reversible displacive phase transitions associated with cooperative rotations of the $\left[\mathrm{BO}_{6}\right]$ octahedra [49]. In particular, $\mathrm{La}_{2} \mathrm{Ti}_{2} \mathrm{O}_{7} \quad\left(=\mathrm{La}_{4} \mathrm{Ti}_{4} \mathrm{O}_{14}, \quad n=4\right)$ undergoes the following sequence of reversible tilting phase transitions on cooling [50]: Amam $\rightarrow A 2_{1} a m \rightarrow$ (incommensurate phase) $\rightarrow P 2_{1}$. For this compound, the Amam $\rightarrow A 2_{1}$ am transition is associated with in-phase rotation of octahedra about the $c$-axis, while the subsequent $A 2_{1} a m \rightarrow P 2_{1}$ symmetry reduction (through

Table 2

Figure of merit: $F_{37}=38.1(0.0084,116)[41]$.
the incommensurate phase) is caused by octahedral tilting about the long $b$-axis; the latter transition doubles the $c$-lattice parameter. A classification scheme that relates the stacking sequences of the $\{110\}$ perovskitelike layers and octahedral tilt systems to the symmetry of the $A_{n} B_{n} \mathrm{O}_{3 n+2}$ structures has been reported previously [49].

Examination of single grains of the $n=5$ compound $\mathrm{La}_{10} \mathrm{MgTi}_{9} \mathrm{O}_{34}$ using electron diffraction indicated doubling of the $c$-parameter (Fig. 5), similar to that observed for the $\mathrm{La}_{2} \mathrm{Ti}_{2} \mathrm{O}_{7}$. The resulting unit cell is monoclinic and the reflection conditions are consistent with the $P 2_{1} / b 11$ space group, which has been commonly reported for other $n=5$ members of $A_{n} B_{n} \mathrm{O}_{3 n+2}$ series; i.e., $\mathrm{Sr}_{5} \mathrm{Nb}_{5} \mathrm{O}_{17}$ and $\mathrm{Ca}_{5} \mathrm{Nb}_{5} \mathrm{O}_{17}$. The unit cell and indexing in Table 5 therefore correspond to the orthorhombic subcell of $\mathrm{La}_{10} \mathrm{MgTi}_{9} \mathrm{O}_{34}$, whereas the actual symmetry of this phase is monoclinic.

Figure of merit: $F_{39}=46.1(0.0113,75)[41]$.

The second new compound, $\mathrm{La}_{9} \mathrm{Mg}_{0.5} \mathrm{Ti}_{8.5} \mathrm{O}_{31}$ (compound $\mathbf{F}$ ), was found to occur between $\mathrm{La}_{10} \mathrm{MgTi}_{9} \mathrm{O}_{34}$ $(n=5)$ and $\mathrm{La}_{2} \mathrm{Ti}_{2} \mathrm{O}_{7}(n=4)$. X-ray powder diffraction data for $\mathrm{La}_{9} \mathrm{Mg}_{0.5} \mathrm{Ti}_{8.5} \mathrm{O}_{31}$ are given in Table 6. All lines could be indexed with an orthorhombic unit cell analogous to the subcell for the " $n=4.5$ " $A_{n} B_{n} \mathrm{O}_{3 n+2}$ homolog in the $\mathrm{SrO}-\mathrm{TiO}_{2}-\mathrm{Nb}_{2} \mathrm{O}_{5}$ system [51], which features perovskite slabs alternately 4 and 5 octahedra in width-the long $b$-dimension of the unit cell is approximately equal to the sum of those for the $n=4$ and $n=5$ compounds. Again, electron diffraction confirmed the actual symmetry of $\mathrm{La}_{9} \mathrm{Mg}_{0.5} \mathrm{Ti}_{8.5} \mathrm{O}_{31}$ to be monoclinic with a doubled $c$-parameter compared to the orthorhombic subcell, as found for $\mathrm{La}_{10} \mathrm{MgTi}_{9} \mathrm{O}_{34}$ and for other $n=4.5$ homologs that form in the

Figure of merit: $F_{59}=70.3(0.0078,107)[41]$.
$\mathrm{La}_{2} \mathrm{Ti}_{2} \mathrm{O}_{7}-\mathrm{CaTiO} 3, \mathrm{Nd}_{2} \mathrm{Ti}_{2} \mathrm{O}_{7}-\mathrm{CaTiO}_{3}$, and $\mathrm{Ca}_{2} \mathrm{Nb}_{2} \mathrm{O}_{7}-$ $\mathrm{CaTiO}_{3}$ systems [15,29,30]. The reflection conditions for $\mathrm{La}_{9} \mathrm{Mg}_{0.5} \mathrm{Ti}_{8.5} \mathrm{O}_{31}$ were consistent with the space group $P 2_{1} / b 11$. The $n=6$ phase commonly found in other systems was not observed to form in the $\mathrm{La}_{2} \mathrm{O}_{3}-\mathrm{MgO}-$ $\mathrm{TiO}_{2}$ system.

### 3.1.3. $(1-x) \operatorname{LaMg}_{1 / 2} \mathrm{Ti}_{1 / 2} \mathrm{O}_{3}-x \mathrm{La}_{2 / 3} \mathrm{TiO}_{3}$ solid solution

This solid solution forms by substitution of $A$-site vacancies for $\mathrm{La}^{3+}$ in $\mathrm{LaMg}_{1 / 2} \mathrm{Ti}_{1 / 2} \mathrm{O}_{3}$ accompanied by an increase in the $\mathrm{Ti}^{4+} / \mathrm{Mg}^{2+}$ ratio according to the formula $\mathrm{La}_{1-x / 3} \square_{\mathrm{x} / 3}\left[\mathrm{Mg}_{(1-x) / 2} \mathrm{Ti}_{(1+x) / 2}\right] \mathrm{O}_{3}, 0.0 \leqslant x \leqslant 0.5$ (phase B, Fig. 2). Since $\mathrm{Ti}^{4+}$ is considerably smaller than $\mathrm{Mg}^{2+}(0.605 \AA$ vs. $0.720 \AA$ ) [52], the cell volume decreases with increasing $x$-value, as seen in Fig. 6; however, the observed non-linearity suggests that the concurrent substitution of $A$-site vacancies has an opposing effect resulting in larger cell volumes than those expected from size effects alone. Other effects such as line splitting in the X-ray powder diffraction patterns indicate systematic changes in unit cell parameters with increasing $x$-value. The dielectric properties occurring in the solid solution are given in Table 1 and Fig. 7. In general, the relative permittivity increases and the temperature coefficient of resonant frequency $\left(\tau_{\mathrm{f}}\right)$ becomes more positive with increasing $x$-value; $\tau_{\mathrm{f}}$ changes sign near $x=0.47$. The data in Fig. 7 suggest a break in slope, with properties abruptly more sensitive to chemical composition above $x=0.4$. A detailed study of this solid solution using electron microscopy combined with variable-temperature X-ray powder diffraction and neutron powder diffraction revealed a sequence of displacive phase transitions associated with rotation of $[(\mathrm{Mg} / \mathrm{Ti}) \mathrm{O}]_{6}$ octahedra; the transition temperatures decrease with increasing $x$. The extent of $B$-site ordering was observed to diminish with increasing $x$, and for $x>0.48$, short-range ordering of $A$-site vacancies was confirmed. The complete results of these studies will be described elsewhere.

As shown in Fig. 2, the $(1-x) \mathrm{LaMg}_{1 / 2} \mathrm{Ti}_{1 / 2} \mathrm{O}_{3}-$ $x \mathrm{La}_{2 / 3} \mathrm{TiO}_{3}$ solid solution line was found to "have width"; i.e., it extends toward the (111) and (110) perovskite-slab compounds ( $\mathbf{D}$ and $\mathbf{E}$, respectively) to form a narrow single-phase region via the occurrence of $B$-site vacancies. $\mathrm{LaMg}_{1 / 2} \mathrm{Ti}_{1 / 2} \mathrm{O}_{3}$ was found to dissolve $\sim 18 \mathrm{~mol} \% \mathrm{La}_{6} \mathrm{MgTi}_{4} \mathrm{O}_{18}$ (with endmembers expressed as $\mathrm{LaO}_{1.5}: \mathrm{MgO}: \mathrm{TiO}_{2}$ mole fractions); essentially no shifts in the $\mathrm{LaMg}_{1 / 2} \mathrm{Ti}_{1 / 2} \mathrm{O}_{3}$ lattice parameters were observed for specimens in this region.

### 3.1.4. Temperature-stable compositions in the $\mathrm{La}_{2} \mathrm{O}_{3}{ }^{-}$ $\mathrm{MgO}-\mathrm{TiO}_{2}$ system

Dielectric properties are additive $[53,54]$ and therefore assemblages of phases with both positive and negative temperature coefficients of resonant frequency $\left(\tau_{f}\right)$ must include temperature-stable $\left(\tau_{\mathrm{f}}=0\right)$ compositions. The

Fig. 3. Suggested crystal structures of trigonal $\mathrm{La}_{5} \mathrm{Mg}_{0.5} \mathrm{Ti}_{3.5} \mathrm{O}_{15}$ (compound $\mathbf{C}$, Table 3) and rhombohedral $\mathrm{La}_{6} \mathrm{Mg}_{0.913} \mathrm{Ti}_{4.04} \mathrm{O}_{18}$ (compound $\mathbf{D}$, Table 4) viewed along the $\langle 110\rangle$ direction. The structures correspond to the $n=5$ and $n=6$ members, respectively, of the "(111) perovskite-slab" homologous series $A_{n} B_{n-1} \mathrm{O}_{3 n}$, with similar $a$-parameters, and $c$-parameters that reflect the number of close-packed layers in the unit cell (five for $n=5$ and eighteen for $n=6$ ). For reasons that are not understood, the $n=6$ compound ( $\mathbf{D}$ ) does not form as a single phase at the ideal stoichiometry of $\mathrm{La}_{6} \mathrm{MgTi}_{4} \mathrm{O}_{18}$; rather, it forms, with no observable solid solution, at the composition indicated, with $1 \% B$-cation vacancies.
existence and approximate locations of these tempera-ture-stable regions can be inferred by mapping the sign of $\tau_{\mathrm{f}}$ onto the phase equilibria diagram, as shown in Fig. 8. (Data for the signs of $\tau_{\mathrm{f}}$ were measured in the present study (Table 1) or were obtained from the literature and other sources $[3,9,14,36,55,56])$. The present data indicate that two $\tau_{\mathrm{f}}=0$ regions occur in the $\mathrm{La}_{2} \mathrm{O}_{3}-\mathrm{MgO}-\mathrm{TiO}_{2}$ system-one near $\mathrm{TiO}_{2}$ (since $\tau_{\mathrm{f}}$ changes sign between $\mathrm{MgTi}_{2} \mathrm{O}_{5}$ and $\mathrm{TiO}_{2}$, and between $\mathrm{La}_{4} \mathrm{Ti}_{9} \mathrm{O}_{24}$ and $\mathrm{La}_{2} \mathrm{Ti}_{2} \mathrm{O}_{7}$ ), and another around the end of the $(1-x) \mathrm{LaMg}_{1 / 2} \mathrm{Ti}_{1 / 2} \mathrm{O}_{3}-x \mathrm{La}_{2 / 3} \mathrm{TiO}_{3}$ solid solution (for which $\tau_{\mathrm{f}}$ becomes positive above $x=0.47$ ), which is in equilibrium with compounds having negative $\tau_{\mathrm{f}}$ values.

## 3.2. $\mathrm{LaMg}_{1 / 2} \mathrm{Ti}_{1 / 2} \mathrm{O}_{3}-\mathrm{CaTiO}_{3}-\mathrm{La}_{2} \mathrm{O}_{3}$ system

This ternary section in the quaternary $\mathrm{La}_{2} \mathrm{O}_{3}-\mathrm{CaO}-$ $\mathrm{MgO}-\mathrm{TiO}_{2}$ system features a large perovskite-related single-phase field bounded by the complete
$\mathrm{LaMg}_{1 / 2} \mathrm{Ti}_{1 / 2} \mathrm{O}_{3}-\mathrm{CaTiO}_{3}$ solid solution and the partial solid solution of $\mathrm{La}_{2} \mathrm{O}_{3}$ in $\mathrm{CaTiO}_{3}$, as shown in Fig. 9. In the present study it was found that $\mathrm{CaTiO}_{3}$ dissolves up to $38 \mathrm{~mol} \% \quad \mathrm{La}_{2} \mathrm{O}_{3}$, forming the solid solution $\mathrm{La}_{2 x} \mathrm{Ca}_{1-2 x}\left[\mathrm{Ca}_{x} \mathrm{Ti}_{1-x}\right] \mathrm{O}_{3}$, with a maximum $x$-value of 0.38 which corresponds to a limiting composition of $\mathrm{La}_{0.76} \mathrm{Ca}_{0.24}\left[\mathrm{Ca}_{0.38} \mathrm{Ti}_{0.62}\right] \mathrm{O}_{3}$. The formation of this solid solution is likely facilitated by the propensity of the slightly smaller $\mathrm{Ca}^{2+}$ ions to occupy both the $A$ - and $B$ sites of the perovskite structure. Earlier work reported that the composition $\mathrm{La}_{4} \mathrm{Ca}_{3} \mathrm{Ti}_{3} \mathrm{O}_{15}(x=0.40)$ was single-phase [37]; however, in the present study this composition contained a small amount of $\mathrm{La}_{2} \mathrm{O}_{3}$ even after extensive re-heating at $1475^{\circ} \mathrm{C}$.

Within the ternary section (Fig. 9) the composition of the perovskite-like phase can be expressed as $\mathrm{La}_{0.5-2 a+2 b}$ $\mathrm{Ca}_{0.5+2 a-2 b}\left[\mathrm{Ca}_{b} \mathrm{Mg}_{0.25-a} \mathrm{Ti}_{0.75+a-b}\right] \mathrm{O}_{3}$, which assumes that cation sites are fully occupied with the larger $\mathrm{La}^{3+}$ ions located in the $A$-sites and with $\mathrm{Ca}^{2+}$ ions occupying

Figure of merit: $F_{97}=35.3(0.0092,298)$ [41].
${ }^{\text {a }}$ Electron diffraction indicated that the actual symmetry of this compound is monoclinic, $P 2_{1} / b 11 ; a \sim 5.5, b \sim 31, c \sim 7.8 \AA ; \beta \sim 104^{\circ}$; however, all peaks observed using X-ray powder diffraction could be indexed using the orthorhombic subcell given here.
both $A$ - and $B$-sites. The value of $a$ can range from 0 through 0.25 , and the $b$-values can range from 0 to a maximum of 0.38 when $a=0.25 .{ }^{3}$ The trends in unit cell volume and distortion of the perovskite structure within the single-phase field are consistent with those observed along the boundaries for the $\mathrm{LaMg}_{1 / 2} \mathrm{Ti}_{1 / 2} \mathrm{O}_{3}-\mathrm{CaTiO}_{3}$ and $\mathrm{La}_{2} \mathrm{O}_{3}-\mathrm{CaTiO}_{3}$ solid solutions: The least distortion is observed for $\mathrm{LaMg}_{1 / 2} \mathrm{Ti}_{1 / 2} \mathrm{O}_{3}$; the distortion increases slightly and the unit cell volume decreases significantly with increasing $\mathrm{CaTiO}_{3}$ content. Dissolution of $\mathrm{La}_{2} \mathrm{O}_{3}$ in

[^3]

Fig. 4. Suggested crystal structure of $\mathrm{La}_{10} \mathrm{MgTi}_{9} \mathrm{O}_{34}$ (compound $\mathbf{E}$, Table 5), isostructural with $\mathrm{Sr}_{5} \mathrm{TiNb}_{4} \mathrm{O}_{17}$, an $n=5$ member of the "(110) perovskite-slab" homologous series $A_{n} B_{n} \mathrm{O}_{3 n+2}$. The $n$-value corresponds to the width, in $\left[\mathrm{BO}_{6}\right]$ octahedra, of the perovskite slabs, which extend parallel to the parent (110) perovskite planes. The orthorhombic subcells for these homologs exhibit similar $a(\sim 5.5 \AA)$ and $c(\sim 3.9 \AA)$ parameters, and variable $b$-parameters that reflect slab thickness and translational symmetry. The refined unit cell for $\mathrm{La}_{9} \mathrm{Mg}_{0.5} \mathrm{Ti}_{8.5} \mathrm{O}_{31}$ (compound $\mathbf{F}$, $\mathrm{Table}_{6}$ ) suggests it is an $n=4.5$ member of this series, with perovskite slabs alternately 4 and 5 octahedra in width.
$\mathrm{CaTiO}_{3}$ results in expanded unit cell volumes and even larger orthorhombic distortions [37,38]-maxima for both are attained in the endmember composition $\mathrm{La}_{0.76} \mathrm{Ca}_{0.24}\left[\mathrm{Ca}_{0.38} \mathrm{Ti}_{0.62}\right] \mathrm{O}_{3}$.

Values for relative permittivity ( $\varepsilon$ ) and temperature coefficient of resonant frequency ( $\tau_{\mathrm{f}}, \mathrm{ppm} /{ }^{\circ} \mathrm{C}$ ) are included in Fig. 9 for several specimens within the perovskite single-phase region (Table 1) [3,38,56]. For the $\mathrm{LaMg}_{1 / 2} \mathrm{Ti}_{1 / 2} \mathrm{O}_{3}-\mathrm{CaTiO}_{3}$ solid solution, $\tau_{\mathrm{f}}$ changes sign at $44: 56 \mathrm{LaMg}_{1 / 2} \mathrm{Ti}_{1 / 2} \mathrm{O}_{3}: \mathrm{CaTiO}_{3}$ (permittivity 48). For the $\mathrm{La}_{2} \mathrm{O}_{3}-\mathrm{CaTiO}_{3}$ solid solution, $\tau_{\mathrm{f}}=0$ occurs near 38:62 $1 / 2 \mathrm{La}_{2} \mathrm{O}_{3}: \mathrm{CaTiO}_{3}$. As seen in Fig. 9, the dotted line through the perovskite single-phase region connects these two compositions and approximately indicates where single-phase, temperature-stable ( $\tau_{\mathrm{f}}=0$ ) compositions are expected to form, with relative permittivities of $40-50$. As confirmed by measurement (Fig. 9, Table 1), specimens on the $\mathrm{CaTiO}_{3}$ side of the dotted $\tau_{\mathrm{f}}=0$ line exhibited positive $\tau_{\mathrm{f}}$-values, while those for specimens on the $\mathrm{La}_{2} \mathrm{O}_{3}$ side were negative.

## 3.3. $\mathrm{LaMg}_{1 / 2} \mathrm{Ti}_{1 / 2} \mathrm{O}_{3}-\mathrm{CaTiO}_{3}-\mathrm{La}_{0.833} \mathrm{Mg}_{0.25} \mathrm{Ti}_{0.75} \mathrm{O}_{3}$ system

This ternary section in the quaternary $\mathrm{La}_{2} \mathrm{O}_{3}-\mathrm{CaO}-$ $\mathrm{MgO}-\mathrm{TiO}_{2}$ system consists of a single-phase perovskitelike field bounded by the solid solutions $\mathrm{LaMg}_{1 / 2} \mathrm{Ti}_{1 / 2} \mathrm{O}_{3}-\mathrm{CaTiO}_{3}, \quad \mathrm{LaMg}_{1 / 2} \mathrm{Ti}_{1 / 2} \mathrm{O}_{3}-\mathrm{La}_{0.833}$ $\mathrm{Mg}_{0.25} \mathrm{Ti}_{0.75} \mathrm{O}_{3}$ (phase B, Fig. 2), and $\mathrm{CaTiO}_{3}-\mathrm{La}_{0.833}$ $\mathrm{Mg}_{0.25} \mathrm{Ti}_{0.75} \mathrm{O}_{3}$, as shown in Fig. 10. $\left(\mathrm{La}_{0.833} \mathrm{Mg}_{0.25}\right.$ $\mathrm{Ti}_{0.75} \mathrm{O}_{3}$ is the endmember of the $(1-x) \mathrm{LaMg}_{1 / 2}$ $\mathrm{Ti}_{1 / 2} \mathrm{O}_{3}-x \mathrm{La}_{2 / 3} \mathrm{TiO}_{3}$ solid solution, $x=0.5$.) Within the single-phase field, the $A$-sites of the perovskite structure are occupied by a mixture of $\mathrm{La}, \mathrm{Ca}$, and vacancies ( $\square$ ), and the $B$-sites are occupied by Mg and Ti according to: $\mathrm{La}_{x} \mathrm{Ca}_{y} \square_{1-x-y}\left[\mathrm{Mg}_{1.5 x+y-1} \mathrm{Ti}_{2-1.5 x-y}\right] \mathrm{O}_{3}$, with $x$ or $y$ ranging from 0 through 1. In Fig. 10, the signs of the temperature coefficients of resonant frequency for the
components are given in parentheses along with $\left(\varepsilon, \tau_{\mathrm{f}}\right)$ values for the temperature-stable $\left(\tau_{\mathrm{f}}=0\right)$ compositions in the $\mathrm{LaMg}_{1 / 2} \mathrm{Ti}_{1 / 2} \mathrm{O}_{3}-\mathrm{CaTiO}_{3}$ and $\mathrm{LaMg}_{1 / 2} \mathrm{Ti}_{1 / 2} \mathrm{O}_{3}-$ $\mathrm{La}_{0.833} \mathrm{Mg}_{0.25} \mathrm{Ti}_{0.75} \mathrm{O}_{3}$ solid solutions. By joining these points, as shown schematically by the dotted line (Fig. 10), the approximate compositions of perovskite-type phases in this section with $\tau_{\mathrm{f}}=0$ and permittivities in the $40-50$ range can be predicted.

The $\mathrm{LaMg}_{1 / 2} \mathrm{Ti}_{1 / 2} \mathrm{O}_{3}-\mathrm{CaTiO}_{3}-\mathrm{La}_{0.833} \mathrm{Mg}_{0.25} \mathrm{Ti}_{0.75} \mathrm{O}_{3}$ plane shown in Fig. 10 and the wedge-shaped singlephase perovskite region shown in Fig. 9 are connected by the $\mathrm{LaMg}_{1 / 2} \mathrm{Ti}_{1 / 2} \mathrm{O}_{3}-\mathrm{CaTiO}_{3}$ solid solution as a common edge - they comprise two sides of an extensive single-phase perovskite-type volume ${ }^{4}$ occurring within the quaternary $\mathrm{La}_{2} \mathrm{O}_{3}-\mathrm{CaO}-\mathrm{MgO}-\mathrm{TiO}_{2}$ system (Fig. 11). Therefore, the dotted $\tau_{\mathrm{f}}=0$ lines in Figs. 9 and 10 (which share a common endpoint at $44: 56$ LMT: $\mathrm{CaTiO}_{3}$ ) are traces of a surface that passes through this volume, locating the compositions of an infinite number of $\tau_{\mathrm{f}}=0$ perovskite-type phases.

## 4. Conclusions

Subsolidus phase relations have been determined for the $\mathrm{La}_{2} \mathrm{O}_{3}-\mathrm{MgO}-\mathrm{TiO}_{2}$ system and for two ternary sections in the quaternary $\mathrm{La}_{2} \mathrm{O}_{3}-\mathrm{CaO}-\mathrm{MgO}-\mathrm{TiO}_{2}$ system. The formation of six ternary phases in the $\mathrm{La}_{2} \mathrm{O}_{3}-\mathrm{MgO}-\mathrm{TiO}_{2}$ system was confirmed. In addition to the previously known compounds $\mathrm{LaMg}_{1 / 2} \mathrm{Ti}_{1 / 2} \mathrm{O}_{3}$, $\mathrm{La}_{5} \mathrm{Mg}_{0.5} \mathrm{Ti}_{3.5} \mathrm{O}_{15}$, and " $\mathrm{La}_{6} \mathrm{MgTi}_{4} \mathrm{O}_{18}$ ", the new phases $\mathrm{La}_{10} \mathrm{MgTi}_{9} \mathrm{O}_{34}$ and $\mathrm{La}_{9} \mathrm{Mg}_{0.5} \mathrm{Ti}_{8.5} \mathrm{O}_{31}$, and the perov-skite-type solid solution $(1-x) \mathrm{LaMg}_{1 / 2} \mathrm{Ti}_{1 / 2} \mathrm{O}_{3}-$

[^4]

Fig. 5. Selected area electron diffraction patterns for $n=5$ type $\mathrm{La}_{10} \mathrm{MgTi}_{9} \mathrm{O}_{34}$ in the (a) [100] and (b) [001] directions. The reflections are indexed according to the orthorhombic subcell (Table 6). The superlattice reflections indicating doubling of the $c$-parameter of the subcell are clearly seen in the [100] orientation. The motif corresponding to the resulting monoclinic superlattice is outlined in (a).
$x \mathrm{La}_{2 / 3} \mathrm{TiO}_{3}(0 \leqslant x \leqslant 0.5)$, were found to form. The latter three phases were probably not observed in the previous study of this system [25] because the reaction temperatures $\left(1200^{\circ} \mathrm{C}\right)$ and times were insufficient to attain equilibrium. In the present study, the phase previously reported as " $\mathrm{La}_{6} \mathrm{MgTi}_{4} \mathrm{O}_{18}$ " formed sluggishly as a single phase only when off-composition, at $\mathrm{La}_{6} \mathrm{Mg}_{0.913} \mathrm{Ti}_{4.04} \mathrm{O}_{18}$, suggesting that the formation of $B$-cation vacancies is required for its stabilization. Indexed X-ray powder diffraction patterns are given for $\mathrm{LaMg}_{1 / 2} \mathrm{Ti}_{1 / 2} \mathrm{O}_{3}, \mathrm{La}_{5} \mathrm{Mg}_{0.5} \mathrm{Ti}_{3.5} \mathrm{O}_{15}, \mathrm{La}_{6} \mathrm{Mg}_{0.913} \mathrm{Ti}_{4.04} \mathrm{O}_{18}$, $\mathrm{La}_{10} \mathrm{MgTi}_{9} \mathrm{O}_{34}$, and $\mathrm{La}_{9} \mathrm{Mg}_{0.5} \mathrm{Ti}_{8.5} \mathrm{O}_{31}$. All ternary crystal chemistry observed in the $\mathrm{La}_{2} \mathrm{O}_{3}-\mathrm{MgO}-\mathrm{TiO}_{2}$ system is

Figure of merit: $F_{109}=17.8(0.0079,773)$ [41].
${ }^{\text {a }}$ Electron diffraction indicated that the actual symmetry of this compound is monoclinic, $P 2_{1} / b 11 . ; a \sim 5.5, b \sim 57, c \sim 7.8 \AA ; \beta \sim 98^{\circ}$; however, all peaks observed using X-ray powder diffraction could be indexed using the orthorhombic subcell given here.
dominated by the perovskite structure or derivatives thereof. $\mathrm{LaMg}_{1 / 2} \mathrm{Ti}_{1 / 2} \mathrm{O}_{3}$ was confirmed to exhibit a monoclinic distorted perovskite structure with 1:1 ordering of the $B$-cations. $\mathrm{La}_{5} \mathrm{Mg}_{0.5} \mathrm{Ti}_{3.5} \mathrm{O}_{15}$ and $\mathrm{La}_{6} \mathrm{Mg}_{0.913} \mathrm{Ti}_{4.04} \mathrm{O}_{18}$ are $n=5$ and $n=6$ members,

Fig. 6. Pseudo-cubic perovskite unit cell volume vs. $x$-value for the $(1-x) \mathrm{LaMg}_{1 / 2} \mathrm{Ti}_{1 / 2} \mathrm{O}_{3}-x \mathrm{La}_{2 / 3} \mathrm{TiO}_{3} \quad$ solid solution $\quad\left(=\mathrm{La}_{1-x / 3} \square_{x / 3}\right.$ $\left[\mathrm{Mg}_{(1-x) / 2} \mathrm{Ti}_{(1+x) / 2}\right] \mathrm{O}_{3}$, where $\square$ denotes $A$-site vacancies); the limiting composition occurs at $x=0.50$. The volumes were calculated from the "(220)" perovskite reflections near $67^{\circ} 2 \theta$. The number of vacancies formed on the $A$-sites and the $\mathrm{Ti}^{4+} / \mathrm{Mg}^{2+}$ ratio on the $B$-sites both increase with $x$-value, but have competing effects on volume, resulting in the observed non-linear behavior.

Fig. 7. Relative permittivity (corrected for porosity, $\varepsilon_{\text {corr }}$; filled circles) and temperature coefficient of resonant frequency ( $\tau_{\mathrm{f}}$, open squares) for the perovskite-related $(1-x) \mathrm{LaMg}_{1 / 2} \mathrm{Ti}_{1 / 2} \mathrm{O}_{3}-x \mathrm{La}_{2 / 3} \mathrm{TiO}_{3}$ solid solution, $0.0 \leqslant x \leqslant 0.50$. With increasing $x$-value, the permittivity increases and the temperature coefficient becomes more positive, changing sign near $x=0.47$. The lines connecting the points serve only as guides for the eye. A detailed study of the structural details accompanying these changes in properties is in progress.
respectively, of the hexagonal series $A_{n} B_{n-1} \mathrm{O}_{3 n}$, which features (111)-cut slabs of the perovskite structure separated by layers of ordered $B$-site vacancies. The new phases $\mathrm{La}_{10} \mathrm{MgTi}_{9} \mathrm{O}_{34}$ and $\mathrm{La}_{9} \mathrm{Mg}_{0.5} \mathrm{Ti}_{8.5} \mathrm{O}_{31}$ are $n=5$ and $n=4.5$ members, respectively, of

Fig. 8. Subsolidus phase relations in the $\mathrm{La}_{2} \mathrm{O}_{3}-\mathrm{MgO}-\mathrm{TiO}_{2}$ system, sign of the temperature coefficient of resonant frequency ( $\tau_{\mathrm{f}}$; in parentheses), and approximate locations of two regions of temperature-stable ( $\tau_{\mathrm{f}}=0$ ) equilibrium mixtures (dotted lines). Since dielectric properties are additive, a mixture of compounds with opposite signs of temperature coefficients, in some proportion(s), will result in a temperature-stable composition. The curvature of the dotted $\tau_{\mathrm{f}}=0$ lines is purely schematic.

Fig. 9. Subsolidus phase equilibria relations in the $\mathrm{LaMg}_{1 / 2} \mathrm{Ti}_{1 / 2} \mathrm{O}_{3}-\mathrm{CaTiO}_{3} \frac{1}{2} \mathrm{La}_{2} \mathrm{O}_{3}$ system as determined in air with synthesis temperatures $\sim 1450^{\circ} \mathrm{C}$. This system features a large perovskite-related single-phase field bounded by the complete $\mathrm{LaMg}_{1 / 2} \mathrm{Ti}_{1 / 2} \mathrm{O}_{3}-\mathrm{CaTiO} \mathrm{O}_{3}$ solid solution and the partial solid solution of $\mathrm{La}_{2} \mathrm{O}_{3}$ in $\mathrm{CaTiO}_{3}$. The formulas for these two solid solutions are shown on the figure. The values for relative permittivity ( $\varepsilon$ ) and temperature coefficient of resonant frequency $\left(\tau_{\mathrm{f}}, \mathrm{ppm} /{ }^{\circ} \mathrm{C}\right)$ are included for a number of specimens. The dotted line, drawn by connecting the $\tau_{\mathrm{f}}=0$ compositions occurring on the boundaries, schematically indicates where single-phase, temperature-stable ( $\tau_{\mathrm{f}}=0$ ) perovskite-like compositions are expected to form with permittivities of 40-50.

Fig. 10. Subsolidus, single-phase perovskite-like field $\mathrm{LaMg}_{1 / 2} \mathrm{Ti}_{1 / 2} \mathrm{O}_{3}-\mathrm{CaTiO}_{3}-\mathrm{La}_{0.833} \mathrm{Mg}_{0.25} \mathrm{Ti}_{0.75} \mathrm{O}_{3}$ within the quaternary system $\mathrm{La}_{2} \mathrm{O}_{3}-\mathrm{CaO}_{-}$ $\mathrm{MgO}-\mathrm{TiO}_{2}$. The side $\mathrm{LaMg}_{1 / 2} \mathrm{Ti}_{1 / 2} \mathrm{O}_{3}-\mathrm{La}_{0.833} \mathrm{Mg}_{0.25} \mathrm{Ti}_{0.75} \mathrm{O}_{3}$ corresponds to the $(1-x) \mathrm{LaMg}_{1 / 2} \mathrm{Ti}_{1 / 2} \mathrm{O}_{3}-x \mathrm{La}_{2 / 3} \mathrm{TiO}$ solid solution, $0.0 \leqslant x \leqslant 0.50$ (phase B, Fig. 2); $\mathrm{La}_{0.833} \mathrm{Mg}_{0.25} \mathrm{Ti}_{0.75} \mathrm{O}_{3}$ corresponds to the limiting composition at $x=0.5$. Signs of the temperature coefficients of resonant frequency $\left(\tau_{\mathrm{f}}\right)$ are indicated in parentheses. The sign of $\tau_{\mathrm{f}}$ changes from negative to positive in both the $\mathrm{LaMg}_{1 / 2} \mathrm{Ti}_{1 / 2} \mathrm{O}_{3}-\mathrm{La}_{2 / 3} \mathrm{TiO}_{3}\left(\mathrm{Table}_{1}\right)$ and $\mathrm{LaMg}_{1 / 2} \mathrm{Ti}_{1 / 2} \mathrm{O}_{3}-\mathrm{CaTiO}_{3}$ solid solutions, as indicated on the figure. The connection of these $\tau_{\mathrm{f}}=0$ points results in the dotted line, which schematically indicates the expected location of single-phase, temperature-stable ( $\tau_{\mathrm{f}}=0$ ) perovskite-like compositions with permittivities of $45-50$.

Fig. 11. Quaternary portion of the $\mathrm{La}_{2} \mathrm{O}_{3}-\mathrm{CaO}-\mathrm{MgO}-\mathrm{TiO}_{2}$ system showing the locations of the ternary sections shown in Figs. 9 and 10. Compound labels on the sides of the tetrahedron have been omitted for clarity. The base corresponds to the $\mathrm{La}_{2} \mathrm{O}_{3}-\mathrm{MgO}-\mathrm{TiO}_{2}$ system (Fig. 1; $\mathrm{LMT}=\mathrm{LaMg}_{1 / 2} \mathrm{Ti}_{1 / 2} \mathrm{O}_{3}$ ). The plane $\mathrm{CaTiO} 3-\mathrm{LMT}-1 / 2 \mathrm{La}_{2} \mathrm{O}_{3}$ corresponds to the section shown in Fig. 9. The plane $\mathrm{CaTiO}_{3}-\mathrm{LMT}-$ $\mathrm{La}_{0.833} \mathrm{Mg}_{0.25} \mathrm{Ti}_{0.75} \mathrm{O}_{3}$ corresponds to the section shown in Fig. 10. These two planes are joined by the vertical line $\mathrm{CaTiO}_{3}-\mathrm{LMT}$ and comprise two sides of an extensive single-phase perovskite-type volume located within the quaternary system. The dotted $\tau_{\mathrm{f}}=0$ lines in Figs. 9 and 10 (which share a common endpoint at $44: 56 \mathrm{LMT}_{\mathrm{LaTiO}}^{3}$ ) are traces of a $\tau_{\mathrm{f}}=0$ surface that passes through this volume, locating the compositions of an infinite number of $\tau_{\mathrm{f}}=0$ perovskite-type phases.
the orthorhombic (110)-cut perovskite-slab series $A_{n} B_{n} \mathrm{O}_{3 n+2}$. Dielectric property measurements (permittivity and temperature coefficient of resonant frequency, $\tau_{\mathrm{f}}$ ) mapped onto the phase equilibria relations indicated two regions in the $\mathrm{La}_{2} \mathrm{O}_{3}-\mathrm{MgO}-\mathrm{TiO}_{2}$ system where temperature-stable ( $\tau_{\mathrm{f}}=0$ ) mixtures or phases can be synthesized. For the $(1-x) \mathrm{LaMg}_{1 / 2} \mathrm{Ti}_{1 / 2} \mathrm{O}_{3}-x \mathrm{La}_{2 / 3} \mathrm{TiO}_{3}$ solid solution, the relative permittivity increases and $\tau_{\mathrm{f}}$ becomes more positive with increasing $x$-value, passing through zero near $x=0.47$; the changes in properties are accompanied by structural changes which will be described elsewhere.
The phase equilibria results obtained for the ternary $\mathrm{La}_{2} \mathrm{O}_{3}-\mathrm{MgO}-\mathrm{TiO}_{2}$ system, which forms one side of the quaternary $\mathrm{La}_{2} \mathrm{O}_{3}-\mathrm{CaO}-\mathrm{MgO}-\mathrm{TiO}_{2}$ system, can be used to project behavior in the higher-order system. For example, the compound $\mathrm{LaMg}_{1 / 2} \mathrm{Ti}_{1 / 2} \mathrm{O}_{3}$ does not occur in equilibrium with the well-known microwave ceramic $\mathrm{MgTiO}_{3}$ (Fig. 1). Therefore, $\mathrm{LaMg}_{1 / 2} \mathrm{Ti}_{1 / 2} \mathrm{O}_{3}: \mathrm{CaTiO}_{3}$ solid solutions with permittivities higher than 50 (and which have small positive $\tau_{\mathrm{f}}$ values) cannot be temperature-compensated by adding $\mathrm{MgTiO}_{3}$ as a second phase because they will not form a stable phase assemblage: instead, mixtures containing MgO and/or $\mathrm{Mg}_{2} \mathrm{TiO}_{4}$ will result, as seen by qualitatively extrapolating the fans of two-phase joins from MgO and $\mathrm{Mg}_{2} \mathrm{TiO}_{4}$ to the $\mathrm{LaMg}_{1 / 2} \mathrm{Ti}_{1 / 2} \mathrm{O}_{3}-\mathrm{La}_{2 / 3} \mathrm{TiO}_{3}$ solid solution (Figs. 1 and 11) into the quaternary system.

Experimental studies of two sections in the quaternary $\mathrm{La}_{2} \mathrm{O}_{3}-\mathrm{CaO}-\mathrm{MgO}-\mathrm{TiO}_{2}$ system found that the only phase that forms in the ternary $\mathrm{LaMg}_{1 / 2} \mathrm{Ti}_{1 / 2} \mathrm{O}_{3}-$ $\mathrm{CaTiO}_{3}-\mathrm{La}_{2} \mathrm{O}_{3}$ section is an extensive perovskite-type solid solution containing a line of temperature-stable $\left(\tau_{\mathrm{f}}=0\right)$ compositions with permittivities in the $40-50$ range. Similarly, the entire section $\mathrm{LaMg}_{1 / 2} \mathrm{Ti}_{1 / 2} \mathrm{O}_{3}-$ $\mathrm{CaTiO}{ }_{3}-\mathrm{La}_{0.833} \mathrm{Mg}_{0.25} \mathrm{Ti}_{0.75} \mathrm{O}_{3}$ consists of a perovskitetype solid solution which also contains a line of temperature-stable ( $\tau_{\mathrm{f}}=0$ ) compositions with permittivities in the $40-50$ range. The lines of $\tau_{\mathrm{f}}=0$ compositions in these two ternary sections are traces of a surface of $\tau_{\mathrm{f}}=0$ compositions that passes through an extensive single-phase, perovskite-type volume occurring in the $\mathrm{La}_{2} \mathrm{O}_{3}-\mathrm{CaO}-\mathrm{MgO}-\mathrm{TiO}_{2}$ system.

## Acknowledgments

The authors appreciate many helpful discussions with R.S. Roth, the assistance of R. Coutts in the preparation of samples, and the efforts of N. Swanson and P.K. Schenck in representation of the phase equilibria data. V.L. Miller was supported by the NSF, DMR program, Research Experiences for Undergraduates (REU).
